

Using black box suite testing, tested each function to ensure that it had the correct output and did what it was intended to. Using `assertTrue`, `assertFalse`, and `assertEquals`, I made sure that edge cases were considered and that the correct data was being created. For example, in `testGetChildren`, I created nodes with label sizes that were in a random order and added them in such a way that ensured they would need to be sorted correctly to get the desired output. Furthermore, I would check if there were duplicate nodes, extra nodes, or missing nodes. These testing methods actually helped me capture, identify, and fix 2 bugs in the code. I ended up adding a test to check for identical child nodes and different labels for this specific function, which was how I identified one of the bugs. I also added a test to ensure that there would be no child nodes in a parent node that was only ever used as a child node.
