

Changes:

This homework was difficult for me because I started it really late and did not manage my time well. When I eventually got down to it, it seemed very overwhelming. Once I switched everything to generics, I began writing my algorithm for legoPaths and tests. Upon running the program, I found that it was taking me 34 seconds to create the graph for lego1970.csv, which is very bad. I decided to completely redo my framework from hw4. This resulted in me removing the child data that was kept in each node, bringing them back to just holding their name once again. I then completely removed the edge class. Finally, I removed the 2 hashsets that stored does and edges in the graph class and instead replaced them with a hashmap that mapped the node names to the nodes themselves and another larger hashmap that represented the graph itself. This large hashmap stored the parent node as the key, and the value was another map. This inner map stored the child node as the key and the value was a hashset containing the edges between the 2 nodes.

Staff Notes:

I honestly cannot complain about the staff on this one. Maybe fixing the gradable and testing it earlier on, but that was about it.

What I wish I knew beforehand:

I wish I knew that the homework was going to take so much time. One thing it would be worth telling students is that hw6 tests the limits of your implementation and forces you to put significant time into making your data structures faster.
