

Changes/Time Management:

During this assignment I changed very little of my previous homeworks. All I did was move my hw6 dijkstra's function into my graph.java file and slightly modify it from there. During my last homework, I was unfortunately EXTREMELY strapped for time and had to use all 5 late days for one assignment to do it. I only managed to get 24/36 on hw6 because I couldn't figure out why my implementation of findPath() was incorrect. Eventually, I figured it out, but it was 2am the following morning meaning I could no longer resubmit. On the brightside, that meant I could easily get 100% on this assignment, which I did in under a day! My hw6 changes were to add a Path class which tracked information on a viable path. For this hw, I added a location class that tracked information on a location such as its name, id, and coordinates. I also created a modelBuilder class to create the model and a new parser class to create the data for the model builder.

Staff Notes:

This assignment was pretty straightforward. However, I would like to point out that it was frustrating to find that while I got EXACTLY the correct outputs for the example files, they were all wrong on submit. Thank god submit told us what was wrong line by line, or else I would have had no idea what the correct output was. Also, in the future when instructing students to use a tab, mention the usage of "/t", as I only used it as a last ditch attempt to debug because most classes frown upon using it.

What I wish I knew beforehand:

I wish I had known prior to this assignment that I would need to call my dijkstra's function, as I would have simply placed it in my graph class from the start instead of developing it originally in my legoPaths class..
